

Body image, Sexual function and Sexual self-schema in gynecological cancer survivors and their partners.

Scientific objective:

A prospective evaluation of the quality of life and sexuality of women after gynaecological cancer treatment and evaluation of predictive factors for the quality of life and sexual health of women after gynaecological cancer treatment.

Justification:

Sexuality of women, who underwent reproductive organ cancer treatment, has only be investigated in a small number of studies. There is also shortage of data, especially from Central and Eastern Europe, on the course of the rehabilitation process and recovery of the patient and her partner's sexual functions. In order to undertake this type of assessment, prospective and long-term studies are warranted.
